# 15. ANOVA for BalancedSplit-Plot Experiments

#### A Traditional Split-Plot Experiment

# A Model for Data from the Traditional Split-Plot Experiment

Genotype i = 1, 2, 3, Fertilizer j = 1, 2, 3, 4, Block k = 1, 2, 3, 4

$$y_{ijk} = \mu_{ij} + b_k + w_{ik} + e_{ijk}$$

 $\mu_{ij} = \text{mean for Genotype } i$ , Fertilizer j

 $b_k = \text{random block effect}$ 

 $w_{ik} = \text{random whole-plot exp. unit effect}$ 

 $e_{iik}$  = random error = random split-plot exp. unit effect

## Table of Means and Marginal Means

|          | Fertilizer Amount   |                     |              |                     |                 |
|----------|---------------------|---------------------|--------------|---------------------|-----------------|
| Genotype | 0                   | 50                  | 100          | 150                 |                 |
| Α        | $\mu_{11}$          | $\mu_{12}$          | $\mu_{13}$   | $\mu_{14}$          | $\bar{\mu}_1$ . |
| В        | $\mu_{21}$          | $\mu_{22}$          | $\mu_{23}$   | $\mu_{24}$          | $\bar{\mu}_2$ . |
| С        | $\mu_{31}$          | $\mu_{32}$          | $\mu_{33}$   | $\mu_{34}$          | $\bar{\mu}_3$ . |
|          | $ar{\mu}_{\cdot 1}$ | $ar{\mu}_{\cdot 2}$ | $ar{\mu}$ .3 | $ar{\mu}_{\cdot 4}$ | $\bar{\mu}$     |

#### **Best Linear Unbiased Estimators**

Because the experiment is balanced, the GLS estimator is equal to the OLS estimator for any estimable  $C\beta$ :

$$C\hat{\boldsymbol{\beta}}_{\Sigma} = C(X'\Sigma^{-1}X)^{-}X'\Sigma^{-1}y = C(X'X)^{-}X'y = C\hat{\boldsymbol{\beta}}.$$

Because the elements of E(y) are  $\{\mu_{ij}: i=1,2,3; j=1,2,3,4\}$ , the estimable quantities are all linear combinations of the cell means  $\{\mu_{ij}: i=1,2,3; j=1,2,3,4\}$ .

The BLUE of  $\sum_{i=1}^{3} \sum_{j=1}^{4} c_{ij} \mu_{ij}$  is  $\sum_{i=1}^{3} \sum_{j=1}^{4} c_{ij} \bar{y}_{ij}$ .

#### Table of Best Linear Unbiased Estimates

|          | Fertilizer Amount     |                       |                    |                           |                   |
|----------|-----------------------|-----------------------|--------------------|---------------------------|-------------------|
| Genotype | 0                     | 50                    | 100                | 150                       |                   |
| Α        | $\bar{y}_{11}$ .      | $\bar{y}_{12}$ .      | $\bar{y}_{13}$ .   | <u> </u> $\bar{y}_{14}$ . | $\bar{y}_{1}$     |
| В        | $\bar{y}_{21}$ .      | $\bar{y}_{22}$ .      | $\bar{y}_{23}$ .   | $\bar{y}_{24}$ .          | $\bar{y}_{2}$     |

|          | $\bar{y}_{\cdot 1}$ . | $\bar{y}_{\cdot 2}$ . | $\overline{y}$ .3. | $\bar{y}$ .4.             | <u> </u> <u> </u> |

## ANOVA Table for the Traditional Split-Plot Design

| Source                            | DF               |   |    |
|-----------------------------------|------------------|---|----|
| Blocks                            | 4 – 1            | = | 3  |
| Genotypes                         | 3 - 1            | = | 2  |
| Blocks 	imes Geno                 | (4-1)(3-1)       | = | 6  |
| Fert                              | 4 - 1            | = | 3  |
| $Geno \times Fert$                | (3-1)(4-1)       | = | 6  |
| $Blocks \times Fert$              | (4-1)(4-1)       |   |    |
| $+Blocks \times Geno \times Fert$ | +(4-1)(3-1)(4-1) | = | 27 |
| C.Total                           | 48 – 1           | = | 47 |

## ANOVA Table for the Traditional Split-Plot Design

| Source                               | DF          |   |    |
|--------------------------------------|-------------|---|----|
| Blocks                               | 4 - 1       | = | 3  |
| Genotypes                            | 3 - 1       | = | 2  |
| $Blocks \times Geno$                 | (4-1)(3-1)  | = | 6  |
| Fert                                 | 4 - 1       | = | 3  |
| $\textit{Geno} \times \textit{Fert}$ | (3-1)(4-1)  | = | 6  |
| Error                                | 3(4-1)(4-1) | = | 27 |
| C.Total                              | 48 - 1      | = | 47 |

## Why does $SS_{Blocks \times Fert} + SS_{Blocks \times Geno \times Fert} = SS_{Error}$ ?

- There are no terms in our model corresponding to Block × Fert combinations; thus, there is no reason to devote a separate line of our ANOVA table to Block × Fert.
- Also, it can be shown that

$$E(MS_{Blocks \times Fert}) = E(MS_{Blocks \times Geno \times Fert}) = \sigma_e^2$$

Thus, it makes sense to estimate  $\sigma_e^2$  with an inverse variance weighted average of independent unbiased estimators:

#### For this slide only, let

 $1 = Blocks \times Fert \text{ and } 2 = Blocks \times Geno \times Fert.$ 

For 
$$\ell=1,2$$
,  $\mathit{MS}_{\ell}\sim \frac{\mathit{E}(\mathit{MS}_{\ell})}{\mathit{df}_{\ell}}\chi^2_{\mathit{df}_{\ell}}\Longrightarrow \mathrm{Var}(\mathit{MS}_{\ell})=2\sigma_e^4/\mathit{df}_{\ell}.$ 

$$\frac{\text{Var}^{-1}(MS_1)MS_1 + \text{Var}^{-1}(MS_2)MS_2}{\text{Var}^{-1}(MS_1) + \text{Var}^{-1}(MS_2)} = \frac{\frac{df_1}{2\sigma_e^4}MS_1 + \frac{df_2}{2\sigma_e^4}MS_2}{\frac{df_1}{2\sigma_e^4} + \frac{df_2}{2\sigma_e^4}}$$

$$= \frac{df_1MS_1 + df_2MS_2}{df_1 + df_2}$$

$$= \frac{SS_1 + SS_2}{df_1 + df_2}$$

Thus, we combine the  $Blocks \times Fert$  and  $Blocks \times Geno \times Fert$  lines of the ANOVA table and label the resulting line as Error.

$$SS_{Blocks \times Fert} + SS_{Blocks \times Geno \times Fert} = SS_{Error}$$

$$df_{Blocks \times Fert} + df_{Blocks \times Geno \times Fert} = df_{Error}$$

$$MS_{Error} = SS_{Error}/df_{Error}$$

$$E(MS_{Error}) = \sigma_e^2$$

Now let's look at the ANOVA table and the analyses that can be done with it in more detail.

#### For greater generality, let

- w = the number of levels of the whole-plot treatment factor,
- s = the number of levels of the split-plot treatment factor, and
- b =the number of blocks.

#### The Test for Whole-Plot Factor Main Effects

To test for genotype main effects, i.e.,

$$H_0: \bar{\mu}_{1.} = \cdots = \bar{\mu}_{w.} \iff H_0: \frac{sb}{w-1} \sum_{i=1}^{w} (\bar{\mu}_{i.} - \bar{\mu}_{..})^2 = 0,$$

compare  $\frac{MS_{Geno}}{MS_{Block \times Geno}}$  to a central F distribution with w-1 and (w-1)(b-1) degrees of freedom.

## Comparison of Whole-Plot Factor Marginal Means

The BLUE of  $\bar{\mu}_{1\cdot} - \bar{\mu}_{2\cdot}$  is  $\bar{y}_{1\cdot\cdot} - \bar{y}_{2\cdot\cdot}$ .

$$\operatorname{Var}(\bar{y}_{1\cdot\cdot\cdot} - \bar{y}_{2\cdot\cdot\cdot}) = \operatorname{Var}(\bar{\mu}_{1\cdot\cdot} - \bar{\mu}_{2\cdot\cdot} + \bar{w}_{1\cdot\cdot} - \bar{w}_{2\cdot\cdot} + \bar{e}_{1\cdot\cdot\cdot} - \bar{e}_{2\cdot\cdot\cdot})$$

$$= \frac{2\sigma_w^2}{b} + \frac{2\sigma_e^2}{sb}$$

$$= \frac{2}{sb}(s\sigma_w^2 + \sigma_e^2) = \frac{2}{sb}E(MS_{Block\times Geno})$$

$$\widehat{\operatorname{Var}}(\bar{y}_{1\cdot\cdot\cdot} - \bar{y}_{2\cdot\cdot\cdot}) = \frac{2}{sb}MS_{Block\times Geno}$$

#### We can use

$$t = \frac{\bar{y}_{1..} - \bar{y}_{2..} - (\bar{\mu}_{1.} - \bar{\mu}_{2.})}{\sqrt{\frac{2}{sb}MS_{Block \times Geno}}} \sim t_{(w-1)(b-1)}$$

to get tests of  $H_0: \bar{\mu}_{1\cdot} = \bar{\mu}_{2\cdot}$  or construct confidence intervals for  $\bar{\mu}_{1\cdot} - \bar{\mu}_{2\cdot}$ .

Furthermore, suppose C is a matrix whose rows are contrast vectors so that C1 = 0. Then

$$\operatorname{Var}\left(\boldsymbol{C}\left[\begin{array}{c} \overline{y}_{1..} \\ \vdots \\ \overline{y}_{w..} \end{array}\right]\right) = \operatorname{Var}\left(\boldsymbol{C}\left[\begin{array}{cccc} \bar{b}_{.} & + & \bar{w}_{1.} & + & \bar{e}_{1..} \\ & & \vdots & & \\ \bar{b}_{.} & + & \bar{w}_{w.} & + & \bar{e}_{w..} \end{array}\right]\right)$$

$$= \operatorname{Var} \left( C \mathbf{1} \bar{b}_{\cdot} + C \begin{bmatrix} \bar{w}_{1\cdot} & + & \bar{e}_{1\cdot\cdot} \\ & \vdots & \\ \bar{w}_{w\cdot} & + & \bar{e}_{w\cdot\cdot} \end{bmatrix} \right) = C \operatorname{Var} \left( \begin{bmatrix} \bar{w}_{1\cdot} & + & \bar{e}_{1\cdot\cdot} \\ & \vdots & \\ \bar{w}_{w\cdot} & + & \bar{e}_{w\cdot\cdot} \end{bmatrix} \right) C'$$

$$= C \left( \frac{\sigma_w^2}{b} + \frac{\sigma_e^2}{sb} \right) IC' = \left( \frac{\sigma_w^2}{b} + \frac{\sigma_e^2}{sb} \right) CC' = \frac{E(MS_{Block \times Geno})}{sb} CC'$$

An F statistic, with q and (w-1)(b-1) degrees of freedom, for testing

$$H_0: oldsymbol{C} egin{bmatrix} ar{\mu}_1. \ dots \ ar{\mu}_{w.} \end{bmatrix} = oldsymbol{0}, ext{ is } \ ar{\mu}_{w.} \end{bmatrix} = oldsymbol{0}, ext{ is } \ ar{U} = egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \end{bmatrix} egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \end{bmatrix} egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \end{pmatrix} egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \end{pmatrix} = egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \end{pmatrix} egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \end{pmatrix} egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \end{pmatrix} egin{bmatrix} ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \ ar{V} \end{pmatrix} egin{bmatrix} ar{V} \ ar{V} \$$

where q is the number of rows of C (which must have full row rank to ensure that the hypothesis is testable).

## Inference for the Split-Plot Factor

$$E(MS_{Fert}) = \frac{wb}{s-1} \sum_{j=1}^{s} E(\bar{y}_{.j.} - \bar{y}_{...})^{2}$$

$$= \frac{wb}{s-1} \sum_{j=1}^{s} E(\bar{\mu}_{.j} - \bar{\mu}_{..} + \bar{e}_{.j.} - \bar{e}_{...})^{2}$$

$$= \frac{wb}{s-1} \sum_{j=1}^{s} (\bar{\mu}_{.j} - \bar{\mu}_{..})^{2} + \sigma_{e}^{2}.$$

Likewise, it can be shown that

$$E(MS_{Error}) = \sigma_e^2$$
.

## The Test for Split-Plot Factor Main Effects

To test for fertilizer main effects, i.e.,

$$H_0: \bar{\mu}_{\cdot 1} = \cdots = \bar{\mu}_{\cdot s} \iff H_0: \frac{wb}{s-1} \sum_{i=1}^{s} (\bar{\mu}_{\cdot j} - \bar{\mu}_{\cdot \cdot})^2 = 0,$$

compare  $\frac{MS_{Fert}}{MS_{Error}}$  to a central F distribution with s-1 and w(s-1)(b-1) degrees of freedom.

# Comparison of Split-Plot Factor Marginal Means

The BLUE of  $\bar{\mu}_{\cdot 1} - \bar{\mu}_{\cdot 2}$  is  $\bar{y}_{\cdot 1} - \bar{y}_{\cdot 2}$ .

$$\bar{y}_{\cdot 1.} - \bar{y}_{\cdot 2.} = (\bar{\mu}_{\cdot 1} + \bar{b}_{\cdot 1} + \bar{w}_{\cdot ..} + \bar{e}_{\cdot 1.}) - (\bar{\mu}_{\cdot 2} + \bar{b}_{\cdot 1} + \bar{w}_{\cdot ..} + \bar{e}_{\cdot 2.})$$

$$Var(\bar{y}_{.1.} - \bar{y}_{.2.}) = Var(\bar{\mu}_{.1} - \bar{\mu}_{.2} + \bar{e}_{.1.} - \bar{e}_{.2.})$$

$$= \frac{2}{wb}\sigma_e^2 = \frac{2}{wb}E(MS_{Error})$$

$$\widehat{\text{Var}}(\bar{y}_{\cdot 1}. - \bar{y}_{\cdot 2}.) = \frac{2}{wb} MS_{Error}$$

#### We can use

$$t = \frac{\bar{y}_{.1.} - \bar{y}_{.2.} - (\bar{\mu}_{.1} - \bar{\mu}_{.2})}{\sqrt{\frac{2}{wb}MS_{Error}}} \sim t_{w(s-1)(b-1)}$$

to get tests of  $H_0: \bar{\mu}_{\cdot 1} = \bar{\mu}_{\cdot 2}$  or to construct confidence intervals for  $\bar{\mu}_{\cdot 1} - \bar{\mu}_{\cdot 2}$ .

Furthermore, suppose C is a matrix with rows that are contrast vectors so that C1 = 0. Then

$$\operatorname{Var}\left(\boldsymbol{C}\begin{bmatrix} \overline{y}_{.1.} \\ \vdots \\ \overline{y}_{.s.} \end{bmatrix}\right) = \operatorname{Var}\left(\boldsymbol{C}\begin{bmatrix} \overline{b}_{.} + \overline{w}_{..} + \overline{e}_{.1.} \\ \vdots \\ \overline{b}_{.} + \overline{w}_{..} + \overline{e}_{.s.} \end{bmatrix}\right)$$

$$= \operatorname{Var}\left(\boldsymbol{C}\mathbf{1}\overline{b}_{.} + \boldsymbol{C}\mathbf{1}\overline{w}_{..} + \boldsymbol{C}\begin{bmatrix} \overline{e}_{.1.} \\ \vdots \\ \overline{e}_{.s.} \end{bmatrix}\right) = \boldsymbol{C}\operatorname{Var}\left(\begin{bmatrix} \overline{e}_{.1.} \\ \vdots \\ \overline{e}_{.s.} \end{bmatrix}\right) \boldsymbol{C}'$$

$$= \boldsymbol{C}\left(\frac{\sigma_{e}^{2}}{wb}\right)\boldsymbol{I}\boldsymbol{C}' = \frac{E(MS_{Error})}{wb}\boldsymbol{C}\boldsymbol{C}'$$

An F statistic, with q and w(s-1)(b-1) degrees of freedom, for testing

$$H_0: C \begin{bmatrix} \bar{\mu}_{.1} \\ \vdots \\ \bar{\mu}_{.s} \end{bmatrix} = \mathbf{0}, \text{ is}$$

$$C \begin{bmatrix} \bar{y}_{.1} \\ \vdots \\ \bar{y}_{.s} \end{bmatrix} \begin{bmatrix} \frac{MS_{Error}}{wb} \mathbf{C} \mathbf{C}' \end{bmatrix}^{-1} \begin{pmatrix} C \begin{bmatrix} \bar{y}_{.1} \\ \vdots \\ \bar{y}_{.s} \end{bmatrix} \end{pmatrix}$$

$$F = \frac{\left( \mathbf{C} \begin{bmatrix} \bar{y}_{.1} \\ \vdots \\ \bar{y}_{.s} \end{bmatrix} \right)' \left[ \frac{MS_{Error}}{wb} \mathbf{C} \mathbf{C}' \right]^{-1} \left( \mathbf{C} \begin{bmatrix} \bar{y}_{.1} \\ \vdots \\ \bar{y}_{.s} \end{bmatrix} \right)}{q}$$

where q is the number of rows of C (which must have full row rank to ensure that the hypothesis is testable).

#### Inference for Interactions

$$E(MS_{Geno\times Fert}) = \frac{b}{(w-1)(s-1)} \sum_{i=1}^{w} \sum_{j=1}^{s} E(\bar{y}_{ij} - \bar{y}_{i..} - \bar{y}_{.j.} + \bar{y}_{...})^{2}$$

$$= \frac{b}{(w-1)(s-1)} \sum_{i=1}^{w} \sum_{j=1}^{s} E(\mu_{ij} - \bar{\mu}_{i.} - \bar{\mu}_{.j} + \bar{\mu}_{..} + \bar{e}_{ij.} - \bar{e}_{i..} - \bar{e}_{.j.} + \bar{e}_{...})^{2}$$

= ...

$$= \frac{b}{(w-1)(s-1)} \sum_{i=1}^{w} \sum_{i=1}^{s} (\mu_{ij} - \bar{\mu}_{i\cdot} - \bar{\mu}_{\cdot j} + \bar{\mu}_{\cdot \cdot})^2 + \sigma_e^2.$$

It can be shown that

$$\mu_{ij} - \bar{\mu}_{i.} - \bar{\mu}_{.j} + \bar{\mu}_{..} = 0 \ \forall \ i,j$$

is equivalent to

$$\mu_{ij} - \mu_{ij^*} - \mu_{i^*j} + \mu_{i^*j^*} = 0 \ \forall \ i \neq i^*, \ j \neq j^*.$$

Thus, 
$$\frac{b}{(w-1)(s-1)} \sum_{i=1}^{w} \sum_{j=1}^{s} (\mu_{ij} - \bar{\mu}_{i.} - \bar{\mu}_{\cdot j} + \bar{\mu}_{..})^2 = 0$$

is equivalent to no interactions between genotypes and fertilizers.

Block × Geno 
$$s\sigma_w^2 + \sigma_e^2$$

Fert 
$$\sigma_e^2 + \frac{wb}{s-1} \sum_{j=1}^s (\bar{\mu}_{\cdot j} - \bar{\mu}_{\cdot \cdot})^2$$

Geno × Fert 
$$\sigma_e^2 + \frac{b}{(w-1)(s-1)} \sum_{i=1}^w \sum_{j=1}^s (\mu_{ij} - \bar{\mu}_{i.} - \bar{\mu}_{.j} + \bar{\mu}_{..})^2$$

Error 
$$\sigma_e^2$$

## The Test for Whole × Split Interaction Effects

To test for genotype  $\times$  fertilizer interaction effects, i.e.,

$$H_0: \mu_{ij} - \bar{\mu}_{i\cdot} - \bar{\mu}_{\cdot j} + \bar{\mu}_{\cdot \cdot} = 0 \ \forall \ i,j \Longleftrightarrow$$

$$H_0: \frac{b}{(w-1)(s-1)} \sum_{i=1}^{w} \sum_{j=1}^{s} (\mu_{ij} - \bar{\mu}_{i\cdot} - \bar{\mu}_{\cdot j} + \bar{\mu}_{\cdot \cdot})^2 = 0,$$

compare  $\frac{MS_{Geno \times Fert}}{MS_{Error}}$  to a central F distribution with (w-1)(s-1) and w(s-1)(b-1) degrees of freedom.

#### Inference for Simple Effects

Consider the difference between two fertilizer means within a genotype, e.g.,  $\mu_{11} - \mu_{12}$  whose BLUE is  $\bar{y}_{11} - \bar{y}_{12}$ .

$$Var(\bar{y}_{11}. - \bar{y}_{12}.) = Var(\mu_{11} - \mu_{12} + \bar{b}. - \bar{b}. + \bar{w}_{1}. - \bar{w}_{1}. + \bar{e}_{11}. - \bar{e}_{12}.)$$
$$= \frac{2}{\hbar}\sigma_{e}^{2}$$

$$\widehat{\text{Var}}(\bar{y}_{11.} - \bar{y}_{12.}) = \frac{2}{b} M S_{Error}$$

#### We can use

$$t = \frac{\bar{y}_{11} - \bar{y}_{12} - (\mu_{11} - \mu_{12})}{\sqrt{\frac{2}{b}MS_{Error}}} \sim t_{w(s-1)(b-1)}$$

to get tests of  $H_0$ :  $\mu_{11} = \mu_{12}$  or construct confidence intervals for  $\mu_{11} - \mu_{12}$ .

Now consider the difference between two genotype means within a fertilizer, e.g.,  $\mu_{11} - \mu_{21}$  whose BLUE is  $\bar{y}_{11} - \bar{y}_{21}$ .

$$\begin{aligned}
\operatorname{Var}(\bar{y}_{11} - \bar{y}_{21}) &= \operatorname{Var}(\mu_{11} - \mu_{21} + \bar{w}_{1.} - \bar{w}_{2.} + \bar{e}_{11.} - \bar{e}_{21.}) \\
&= \frac{2\sigma_{w}^{2}}{b} + \frac{2\sigma_{e}^{2}}{b} \\
&= \frac{2}{b}(\sigma_{w}^{2} + \sigma_{e}^{2}).
\end{aligned}$$

This variance is not a constant times any expected mean square from our ANOVA table.

#### We need an estimator of $\sigma_w^2 + \sigma_e^2$ . We have

$$E(MS_{Block \times Geno}) = s\sigma_w^2 + \sigma_e^2, \quad E(MS_{Error}) = \sigma_e^2, \quad \text{and}$$

$$E\left(\frac{1}{s}MS_{Block\times Geno} + \frac{s-1}{s}MS_{Error}\right) = \sigma_w^2 + \frac{\sigma_e^2}{s} + \frac{(s-1)\sigma_e^2}{s}$$
$$= \sigma_w^2 + \sigma_e^2.$$

Thus,

$$\frac{1}{s}MS_{Block\times Geno} + \frac{s-1}{s}MS_{Error}$$

is an unbiased estimator of  $\sigma_w^2 + \sigma_e^2$ .

It follows that

$$\widehat{\text{Var}}(\bar{y}_{11.} - \bar{y}_{21.}) \equiv \frac{2}{sb} MS_{Block \times Geno} + \frac{2(s-1)}{sb} MS_{Error}$$

is an unbiased estimator of  $Var(\bar{y}_{11} - \bar{y}_{21})$ .

We can use

$$\frac{\bar{y}_{11\cdot} - \bar{y}_{21\cdot} - (\mu_{11} - \mu_{21})}{\sqrt{\widehat{\mathrm{Var}}(\bar{y}_{11\cdot} - \bar{y}_{21\cdot})}} \; \stackrel{\cdot}{\sim} \; t_d, \; \; \text{with } d \; \text{degrees of freedom}$$

computed by Cochran-Satterthwaite to get approximate tests of  $H_0: \mu_{11} = \mu_{21}$  or to construct approximate confidence intervals for  $\mu_{11} = \mu_{21}$ .

## Full Table of Expected Mean Squares

| Source                               | Expected Mean Squares   |
|--------------------------------------|---|
| Block                                | $ws\sigma_b^2 + s\sigma_w^2 + \sigma_e^2$   |
| Geno                                 | $s\sigma_w^2 + \sigma_e^2 + \frac{sb}{w-1} \sum_{i=1}^w (\bar{\mu}_{i.} - \bar{\mu}_{})^2$                                  |
| $Block \times Geno$                  | $s\sigma_w^2 + \sigma_e^2$  |
| Fert                                 | $\sigma_e^2 + \frac{wb}{s-1} \sum_{j=1}^s (\bar{\mu}_{\cdot j} - \bar{\mu}_{\cdot \cdot})^2$                                |
| $\textit{Geno} \times \textit{Fert}$ | $\sigma_e^2 + \frac{b}{(w-1)(s-1)} \sum_{i=1}^w \sum_{j=1}^s (\mu_{ij} - \bar{\mu}_{i.} - \bar{\mu}_{.j} + \bar{\mu}_{})^2$ |
| Error                                | $\sigma_e^2$  |

## Inferences for Cell Mean $\mu_{ij}$

$$\operatorname{Var}(\bar{y}_{ij\cdot}) = \operatorname{Var}(\mu_{ij} + \bar{b}_{\cdot} + \bar{w}_{i\cdot} + \bar{e}_{ij\cdot})$$
$$= \frac{\sigma_b^2}{b} + \frac{\sigma_w^2}{b} + \frac{\sigma_e^2}{b}$$

We can construct the unbiased estimator

$$\widehat{\text{Var}}(\bar{y}_{ij.}) = \frac{1}{wbs} \left[ MS_{Block} + (w-1) MS_{Block \times Geno} + w(s-1) MS_{Error} \right]$$

with approximate degrees of freedom from Cochran-Satterthwaite.

#### Inferences for Whole-Plot-Factor Means $\bar{\mu}_{i}$ .

$$Var(\bar{y}_{i\cdot\cdot}) = Var(\bar{\mu}_{i\cdot} + \bar{b}_{\cdot} + \bar{w}_{i\cdot} + \bar{e}_{i\cdot\cdot})$$
$$= \frac{\sigma_b^2}{b} + \frac{\sigma_w^2}{b} + \frac{\sigma_e^2}{sb}$$

This can be estimated with a linear combination of mean squares.

If block effects are considered fixed rather than random,

$$Var(\bar{y}_{i..}) = Var(\bar{\mu}_{i.} + \bar{b}_{.} + \bar{w}_{i.} + \bar{e}_{i..})$$

$$= \frac{\sigma_{w}^{2}}{b} + \frac{\sigma_{e}^{2}}{sb}$$

$$= \frac{1}{sb} (s\sigma_{w}^{2} + \sigma_{e}^{2})$$

We can estimate this variance by  $\frac{1}{sb}MS_{Block\times Geno}$  with (w-1)(b-1) degrees of freedom.

# Inferences for Split-Plot-Factor Means $\bar{\mu}_{\cdot j}$

If block effects are considered random,

$$\operatorname{Var}(\bar{y}_{\cdot j \cdot}) = \operatorname{Var}(\bar{\mu}_{\cdot j} + \bar{b}_{\cdot} + \bar{w}_{\cdot \cdot} + \bar{e}_{\cdot j \cdot})$$
$$= \frac{\sigma_b^2}{b} + \frac{\sigma_w^2}{wb} + \frac{\sigma_e^2}{wb}$$

If block effects are considered fixed,

$$\operatorname{Var}(\bar{y}_{\cdot j \cdot}) = \operatorname{Var}(\bar{\mu}_{\cdot j} + \bar{b}_{\cdot} + \bar{w}_{\cdot \cdot} + \bar{e}_{\cdot j \cdot})$$
$$= \frac{\sigma_{w}^{2}}{wh} + \frac{\sigma_{e}^{2}}{wh}.$$

Both can be estimated by linear combinations of mean squares.

#### Summary of ANOVA for a Balanced Split-Plot

- Use whole-plot-error mean square for inferences on
  - contrasts among whole-plot-factor marginal means
- Use split-plot-error mean square for inferences on
  - contrasts among split-plot-factor marginal means
  - whole× split interactions
  - a simple effect within a whole-plot treatment
- Construct a linear combination of mean squares for inferences on
  - a simple effect within a split-plot treatment
  - a comparison within neither whole-plot nor split-plot treatments (e.g.,  $\mu_{11} \mu_{22}$ )
  - most means
